# Goals of COMALE: Composite Of Markovian Likelihoods for Experimental evolution

# Simulations

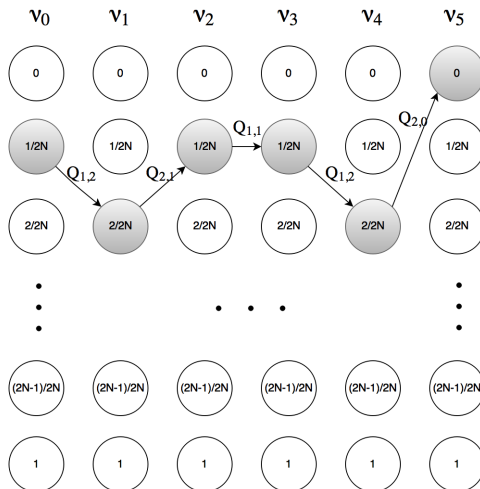

# Case I: Exact Allele Frequency

- Given allele frequencies  $\{\nu_0, \dots, \nu_T\}$  at each site compute  $\lambda$ -statistic for each SNP by

$$\lambda = \frac{H_1}{H_0} = \frac{\Pr(\nu_0, \dots, \nu_T | s = s^*)}{\Pr(\nu_0, \dots, \nu_T | s = 0)} \quad (1)$$

where  $s^*$  is the maximum likelihood estimate of  $s$  (strength of selection).

# Probability of a Sequence: Wright-Fisher Markov Chain

$$P(v_0, \dots, v_5) = Q_{1,2} Q_{2,1} Q_{1,1} Q_{1,2} Q_{2,0}$$

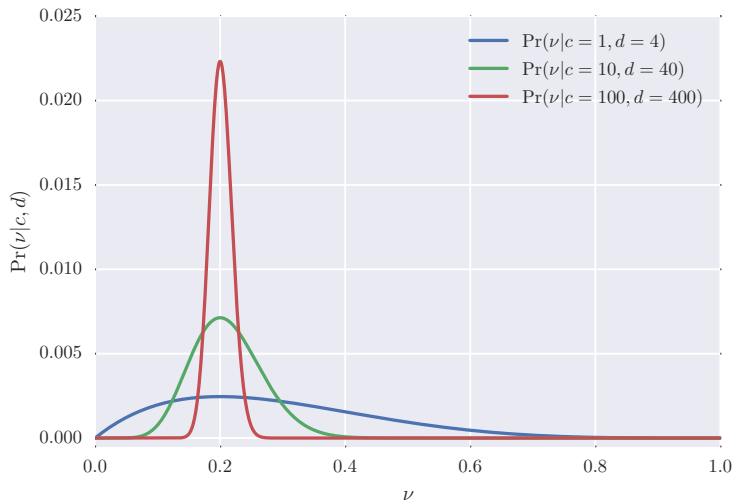

# Model vs Observation

# Depth Heterogeneity

# Uncertainty in allele frequency

## Case II: Unknown Allele Frequency (Pooled-Seq data)

- Given  $\{x_0, \dots, x_T\}$  at each site where  $x_t = (c_t, d_t)$  is a tuple of derived allele read count and the read depth, we are interested in computing  $\lambda$ -statistic for each SNP by

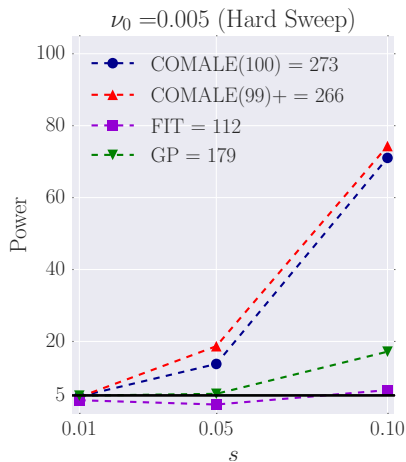

$$\lambda = \frac{H_1}{H_0} = \frac{\Pr(x_0, \dots, x_T | s = s^*)}{\Pr(x_0, \dots, x_T | s = 0)} \quad (2)$$

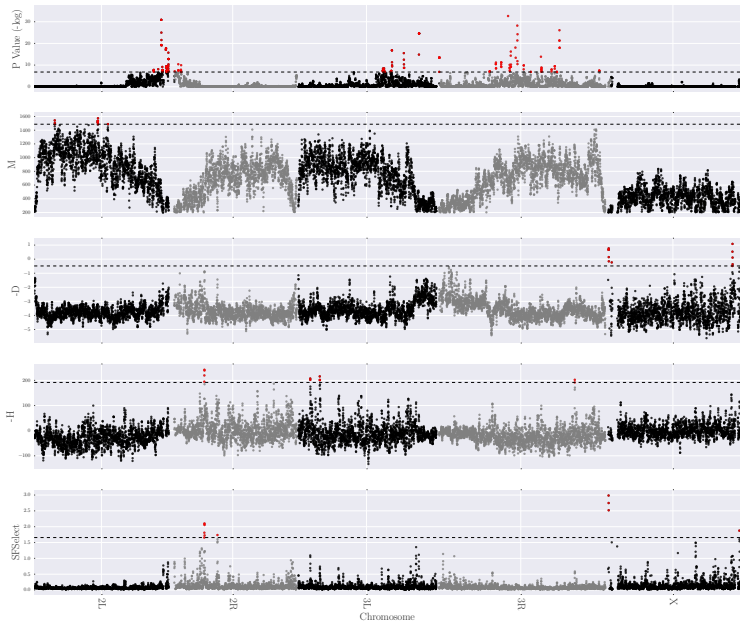

- Hidden Markov Model computes null and alternative likelihoods.

# COMALE statistic and P-Value for a region

- Having computed  $\mathcal{L} = \{\lambda_1, \dots, \lambda_M\}$  for each SNP of a region, COMALE is the average of top-10 elements.
- P-Value of the COMALE statistic is computed under empirical null distribution, i.e., negative control.
